

Acute Bronchitis by droplets

Christodoulou Eleni

Istanbul University, Turkey

Abstract

Bronchitis is a respiratory disease caused by inflammation of the inner walls of the lungs. A common cause of acute bronchitis is a viral or bacterial infection, but other causes can be irritants such as tobacco, smoke, and air pollution. For example, the symptoms of bronchitis are also symptoms of asthma, but there are also wheezing and shortness of breath. Bronchitis has a slight fever, but asthma does not. There are two sorts of bronchitis, unremitting and intense. Persistent bronchitis may be a long-term aggravation of the shallow lining of the bronchi. It is frequently caused by smoking cigarettes, but it can be caused by drawn out presentation to destructive aggravations. It is as a rule not infectious and cannot be gotten from or passed on to others. Individuals in this condition hack, but in the event that they are in near contact when hacking, they may not hack unless the cause is a contamination.
